

# On the Generalization of Models Trained with SGD: Information-Theoretic Bounds and Implications

Ziqiao Wang<sup>1</sup>      Yongyi Mao<sup>1</sup>

<sup>1</sup>University of Ottawa

December 3, 2021

# Motivation

- ▶ Generalization measures (e.g., VC-dim and Rademacher complexity) in classical statistical learning theory cannot explain the success of modern deep neural networks.

# Motivation

- ▷ Generalization measures (e.g., VC-dim and Rademacher complexity) in classical statistical learning theory cannot explain the success of modern deep neural networks.

# of parameters > # of training data & can even perfectly fit random labels

⇒ high capacity

⇒ still perform well on unseen data

# Motivation

- ▶ Algorithm & Distribution-dependent ⇒ non-vacuous generalization bound
- ▶ Does the flatness have impact on the generalization?

Our work follows up on a recent work of

*Gergely Neu, Gintare Karolina Dziugaite, Mahdi Haghifam, and Daniel M Roy. Information theoretic generalization bounds for stochastic gradient descent. In COLT, 2021*

# Problem Setup

- ▶ Training dataset:  $S = \{Z_i\}_{i=1}^n \in \mathcal{Z}$ , drawn i.i.d. from  $\mu$
- ▶ Hypothesis space:  $\mathcal{W} \subseteq \mathbb{R}^d$
- ▶ Learning algorithm:  $\mathcal{A} : \mathcal{Z}^n \rightarrow \mathcal{W}$  by  $P_{W|S}$
- ▶ Loss:  $\ell : \mathcal{W} \times \mathcal{Z} \rightarrow \mathbb{R}^+$
- ▶ We're interested in
  - ▶ Population risk:  $L_\mu(w) \triangleq \mathbb{E}_{Z \sim \mu}[\ell(w, Z)]$
  - ▶ Empirical risk:  $L_S(w) \triangleq \frac{1}{n} \sum_{i=1}^n \ell(w, Z_i)$
  - ▶ Expected generalization error:  $\text{gen}(\mu, P_{W|S}) \triangleq \mathbb{E}_{W, S}[L_\mu(W) - L_S(W)]$

## Lemma 1 (Thm 1., Xu&Raginsky'2017)

Assume the loss  $\ell(w, Z)$  is  $R$ -subgaussian<sup>a</sup> for any  $w \in \mathcal{W}$ . The generalization error of  $\mathcal{A}$  is bounded by

$$|\text{gen}(\mu, P_{W|S})| \leq \sqrt{\frac{2R^2}{n} I(W; S)},$$

---

<sup>a</sup>A random variable  $X$  is  $R$ -subgaussian if for any  $\rho$ ,  $\log \mathbb{E} \exp(\rho(X - \mathbb{E}X)) \leq \rho^2 R^2 / 2$ .

Mutual information  $I(W; S) \triangleq \mathbf{D}_{\text{KL}}(P_{W,S} || P_W \otimes P_S)$ .

⇒ Distribution-dependent and Algorithm-dependent

# Stochastic Gradient Descent (SGD)

SGD updates:

$$W_t \triangleq W_{t-1} - \lambda_t g(W_{t-1}, B_t),$$

where

$$g(w, B_t) \triangleq \frac{1}{b} \sum_{z \in B_t} \nabla_w \ell(w, z),$$

- ▶  $\lambda_t$ : learning rate
- ▶  $b$ : batch size
- ▶  $B_t$  denotes the batch used for the  $t^{\text{th}}$  update.

Assume SGD outputs  $W_T$  as the learned model parameter.

# Stochastic Gradient Descent (SGD)

SGD updates:

$$W_t \triangleq W_{t-1} - \lambda_t g(W_{t-1}, B_t),$$

where

$$g(w, B_t) \triangleq \frac{1}{b} \sum_{z \in B_t} \nabla_w \ell(w, z),$$

- ▶  $\lambda_t$ : learning rate
- ▶  $b$ : batch size
- ▶  $B_t$  denotes the batch used for the  $t^{\text{th}}$  update.

Assume SGD outputs  $W_T$  as the learned model parameter.

**Difficulty of using Xu's bound:  $I(W_T; S) \rightarrow \infty$  in some cases**

# Auxiliary Weight Process (only exists in the analysis)

Let  $\sigma_1, \sigma_2, \dots, \sigma_T$  be a sequence of positive real numbers.

Define

$$\tilde{W}_0 \triangleq W_0, \quad \text{and} \quad \tilde{W}_t \triangleq \tilde{W}_{t-1} - \lambda_t g(W_{t-1}, B_t) + N_t, \quad \text{for } t > 0,$$

where  $N_t \sim \mathcal{N}(0, \sigma_t^2 \mathbf{I}_d)$  is a Gaussian noise.

$$\begin{array}{ccccccccccc} & & N_1 & & N_2 & & \cdots & & N_{T-1} & & N_T \\ & & \downarrow & & \downarrow & & & & \downarrow & & \downarrow \\ \tilde{W}_0 & \rightarrow & \tilde{W}_1 & \rightarrow & \tilde{W}_2 & \rightarrow & \cdots & \rightarrow & \tilde{W}_{T-1} & \rightarrow & \tilde{W}_T \\ \parallel & \nearrow & & \nearrow & & \nearrow & & & & \nearrow & \\ W_0 & \rightarrow & W_1 & \rightarrow & W_2 & \rightarrow & \cdots & \rightarrow & W_{T-1} & \rightarrow & W_T \end{array}$$

Let  $\Delta_t = \sum_{\tau=1}^t N_\tau$ . Notice that  $\tilde{W}_t = W_t + \Delta_t$ .

# Xu's bound (Lemma 1) for noisy, iterative algorithm

- ▶ Learning algorithm  $\tilde{A}$  takes  $S$  as input and outputs  $\tilde{W}$
- ▶ Decomposition of the expected generalization gap:

$$\begin{aligned} & |\text{gen}(\mu, P_{W_T|S})| \\ &= |\mathbb{E}_{W,S}[L_\mu(W_T) - L_S(W_T)]| \\ &= \left| \mathbb{E}_{W,S,\Delta}[L_\mu(W_T) - L_S(W_T) + L_\mu(\tilde{W}_T) - L_S(\tilde{W}_T) - L_\mu(\tilde{W}_T) + L_S(\tilde{W}_T)] \right| \\ &= \left| \text{gen}(\mu, P_{\tilde{W}_T|S}) + \mathbb{E}_{W_T,\Delta_T}[L_\mu(W_T) - L_\mu(\tilde{W}_T)] + \mathbb{E}_{W_T,\Delta_T,S}[L_S(\tilde{W}_T) - L_S(W_T)] \right|. \end{aligned}$$

# Xu's bound (Lemma 1) for noisy, iterative algorithm

- ▶ Learning algorithm  $\tilde{A}$  takes  $S$  as input and outputs  $\tilde{W}$
- ▶ Decomposition of the expected generalization gap:

$$\begin{aligned} & |\text{gen}(\mu, P_{W_T|S})| \\ &= |\mathbb{E}_{W,S}[L_\mu(W_T) - L_S(W_T)]| \\ &= \left| \mathbb{E}_{W,S,\Delta}[L_\mu(W_T) - L_S(W_T) + L_\mu(\tilde{W}_T) - L_S(\tilde{W}_T) - L_\mu(\tilde{W}_T) + L_S(\tilde{W}_T)] \right| \\ &= \left| \text{gen}(\mu, P_{\tilde{W}_T|S}) + \mathbb{E}_{W_T,\Delta_T}[L_\mu(W_T) - L_\mu(\tilde{W}_T)] + \mathbb{E}_{W_T,\Delta_T,S}[L_S(\tilde{W}_T) - L_S(W_T)] \right|. \end{aligned}$$

$$\implies |\text{gen}(\mu, P_{\tilde{W}_T|S})| \leq \sqrt{\frac{2R^2}{n} I(\tilde{W}_T; S)} < \infty$$

# Information-theoretic bound for SGD

## Lemma 2 (Thm.1, Neu et al'2021)

The generalization error of SGD is upper bounded by

$$|\text{gen}(\mu, P_{W_T|S})| \leq \sqrt{\frac{4R^2}{n} \sum_{t=1}^T \frac{\lambda_t^2}{\sigma_t^2} \mathbb{E} [\Psi(W_{t-1}) + \tilde{\mathbb{V}}_t(W_{t-1})]} + |\mathbb{E} [\gamma(W_T, S) - \gamma(W_T, S')]|$$

where

- ▶ Local gradient sensitivity:

$$\Psi(w_{t-1}) \triangleq \mathbb{E} [\|\nabla_w \ell(w_{t-1}, Z) - \nabla_w \ell(w_{t-1} + \zeta, Z)\|_2^2], \zeta \sim \mathcal{N}(0, 2 \sum_{i=1}^{t-1} \sigma_i^2 \mathbf{I}_d)$$

- ▶ Gradient Dispersion/Variance:  $\tilde{\mathbb{V}}_t(w) \triangleq \mathbb{E} [\|g(w, B_t) - \mathbb{E} [\nabla_w \ell(w, Z)]\|_2^2]$

- ▶ Local value sensitivity:  $\gamma(w, s) \triangleq \mathbb{E} [L_s(w + \Delta_T) - L_s(w)]$

# Our main result

Let  $\mathbb{V}_t(w) \triangleq \mathbb{E} [\|g(w, B_t) - \mathbb{E} [\nabla_w \ell(W, Z)]\|_2^2]$ .

## Theorem 1

*The generalization error of SGD is upper bounded by*

$$|\text{gen}(\mu, P_{W_T|S})| \leq \sqrt{\frac{R^2}{n} \sum_{t=1}^T \frac{\lambda_t^2}{\sigma_t^2} \mathbb{E} [\mathbb{V}_t(W_{t-1})] + |\mathbb{E} [\gamma(W_T, S) - \gamma(W_T, S')]|}. \quad (1)$$

*Assume  $L_\mu(w_T) \leq \mathbb{E}_\Delta [L_\mu(w_T + \Delta_T)]$  and  $\sigma_t^2$  is independent of  $t$ . Denote by  $H_{W_T}$  the Hessian of the loss with respect to  $W_T$  and let  $\text{Tr}(\cdot)$  denote trace. Then*

$$\text{gen}(\mu, P_{W_T|S}) \leq \frac{3}{2} \left( \sum_{t=1}^T \frac{R^2 \lambda_t^2 T}{n} \mathbb{E} [\mathbb{V}_t(W_{t-1})] \mathbb{E} [\text{Tr}(H_{W_T}(Z))] \right)^{\frac{1}{3}} \quad (2)$$

$$|\text{gen}(\mu, P_{W_T|S})| \leq \sqrt{\frac{R^2}{n} \sum_{t=1}^T \frac{\lambda_t^2}{\sigma_t^2} \mathbb{E}[\mathbb{V}_t(W_{t-1})] + |\mathbb{E}[\gamma(W_T, S) - \gamma(W_T, S')]|}.$$

- ▶ The first term: “trajectory term”; The second term: “flatness term”

$$|\text{gen}(\mu, P_{W_T|S})| \leq \sqrt{\frac{R^2}{n} \sum_{t=1}^T \frac{\lambda_t^2}{\sigma_t^2} \mathbb{E} [\mathbb{V}_t(W_{t-1})] + |\mathbb{E} [\gamma(W_T, S) - \gamma(W_T, S')]|}.$$

- ▶ The first term: “trajectory term”; The second term: “flatness term”
- ▶ Our bound improves the bound in Lemma 2:

(a)  $\sigma = 10^{-5}$  (MNIST)

(b)  $\sigma = 10^{-6}$  (MNIST)

(c)  $\sigma = 10^{-5}$  (CIFAR10)

(d)  $\sigma = 10^{-6}$  (CIFAR10)

This improvement should come at no surprise, since  $\Psi(W_{t-1})$  has the cumulative variance  $2 \sum_{i=1}^{t-1} \sigma_i^2 \mathbf{I}_d$

$$\text{gen}(\mu, P_{W_T|S}) \leq \frac{3}{2} \left( \sum_{t=1}^T \frac{R^2 \lambda_t^2 T}{n} \mathbb{E} [\mathbb{V}_t(W_{t-1})] \mathbb{E} [\text{Tr}(\mathbf{H}_{W_T}(Z))] \right)^{\frac{1}{3}}$$

- ▶ Condition  $L_\mu(w_T) \leq \mathbb{E}_{\Delta_T} [L_\mu(w_T + \Delta_T)] \implies$  the perturbation does not decrease the population risk.

Also assumed in [Foret, et al.'2021] in the derivation of a PAC-Bayesian bound.

$$\text{gen}(\mu, P_{W_T|S}) \leq \frac{3}{2} \left( \sum_{t=1}^T \frac{R^2 \lambda_t^2 T}{n} \mathbb{E} [\mathbb{V}_t(W_{t-1})] \mathbb{E} [\text{Tr}(\mathbf{H}_{W_T}(Z))] \right)^{\frac{1}{3}}$$

- ▶ Condition  $L_\mu(w_T) \leq \mathbb{E}_{\Delta_T} [L_\mu(w_T + \Delta_T)] \implies$  the perturbation does not decrease the population risk.  
Also assumed in [Foret, et al.'2021] in the derivation of a PAC-Bayesian bound.
- ▶ Eq.2 follows from Eq.1 by minimizing the bound over  $\sigma$ .  
Eq.2 **can be computed easily and efficiently**.

# Application: Linear Networks

Regression setting:

- ▷  $Z = (X, Y)$
- ▷  $X \in \mathbb{R}^{d_0}$ ; Assume  $\|X\| = 1$
- ▷ Model  $f(W, \cdot) : \mathbb{R}^{d_0} \rightarrow \mathbb{R}$
- ▷  $\ell(W, Z) = 1/2(Y - f(W, X))^2$

## Theorem 2 (Linear Networks)

Let  $f(W, X) = W^T X$ . Then,

$$\text{gen}(\mu, P_{W_T|S}) \leq 3 \left( \sum_{t=1}^T \frac{R^2 \lambda_t^2 T}{4n} \mathbb{E} [\ell(W_{t-1}, Z)] \right)^{\frac{1}{3}}.$$

# Application: Two-Layer ReLU Networks

## Theorem 3 (Two-Layer ReLU Networks)

Following [Arora et al'2019], consider  $f(W, X) = \frac{1}{\sqrt{m}} \sum_{r=1}^m A_r \text{ReLU}(W_r^T X)$  where  $A_r \sim \text{unif}(\{+1, -1\})$ . We fix the second layer parameters during training. Then,

$$\text{gen}(\mu, P_{W_T|S}) \leq 3 \left( \sum_{r=1}^m \mathbb{E} \left[ \frac{\mathbb{I}_{r,i,T}}{m} \right] \sum_{t=1}^T \frac{R^2 \lambda_t^2 T}{4n} \mathbb{E} \left[ \sum_{r=1}^m \frac{\mathbb{I}_{r,i,t}}{m} \ell(W_{t-1}, Z) \right] \right)^{\frac{1}{3}},$$

where  $\mathbb{I}_{r,i,t} = \mathbb{I}\{W_{t-1,r}^T X_i \geq 0\}$  and  $\mathbb{I}$  is the indicator function.

⇒ Sparsely activated ReLU networks are expected to generalize better.

# Experiment: Bound Verification of Thm 1

(g) noise=0.4 (CIFAR10)

(h) noise=0.6 (CIFAR10)

Figure 2: Dynamics of gradient dispersion, in relation to training/testing accuracy.

# Three Learning Phases

- ▷  $\nabla$  rapidly descends; Both training acc. and test acc. increase;  $\implies$  “Generalization”
- ▷  $\nabla$  starts increasing until it reaches a peak value; Training acc. and testing acc. gradually diverge;  $\implies$  “Memorization”
- ▷  $\nabla$  descends again; Training and testing curves reach their respective maximum and minimum.

# Implication: Dynamic Gradient Clipping

---

## Algorithm 1 Dynamic Gradient Clipping

---

**Require:** Training set  $S$ , Batch size  $b$ , Loss function  $\ell$ , Initial model parameter  $w_0$ , Learning rate  $\lambda$ , Initial minimum gradient norm  $\mathcal{G}$ , Number of iterations  $T$ , Clipping parameter  $\alpha$ , Clipping step  $T_c$

```
1: for  $t \leftarrow 1$  to  $T$  do
2:   Sample  $\mathcal{B} = \{z_i\}_{i=1}^b$  from training set  $S$ 
3:   Compute gradient:
4:    $g_{\mathcal{B}} \leftarrow \sum_{i=1}^b \nabla_w \ell(w_{t-1}, z_i) / b$ 
5:   if  $t > T_c$  then
6:     if  $\|g_{\mathcal{B}}\|_2 > \mathcal{G}$  then
7:        $g_{\mathcal{B}} \leftarrow \alpha \cdot \mathcal{G} \cdot g_{\mathcal{B}} / \|g_{\mathcal{B}}\|_2$ 
8:     else
9:        $\mathcal{G} \leftarrow \|g_{\mathcal{B}}\|_2$ 
10:    end if
11:  Update parameter:  $w_t \leftarrow w_{t-1} - \lambda \cdot g_{\mathcal{B}}$ 
12: end for
```

- 12: **end for**

(a) noise=0.2 (MNIST)

(b) noise=0.4 (MNIST)

(c) noise=0.2 (CIFAR10)

(d) noise=0.4 (CIFAR10)

# Implication: Gaussian Model Perturbation (GMP)

- ▶ We hope the empirical risk surface at  $w^*$  is flat, or insensitive to a small perturbation of  $w^*$ .

$$\min_w L_s(w) + \rho \mathbb{E}_{\Delta \sim \mathcal{N}(0, \sigma^2 \mathbf{I}_d)} [L_s(w + \Delta) - L_s(w)],$$

where  $\rho$  is a hyper-parameter.

# Implication: Gaussian Model Perturbation (GMP)

- ▶ We hope the empirical risk surface at  $w^*$  is flat, or insensitive to a small perturbation of  $w^*$ .

$$\min_w L_s(w) + \rho \mathbb{E}_{\Delta \sim \mathcal{N}(0, \sigma^2 \mathbf{I}_d)} [L_s(w + \Delta) - L_s(w)],$$

where  $\rho$  is a hyper-parameter.

- ▶ Replacing the expectation above with its stochastic approximation using  $k$  realizations of  $\Delta$  gives rise to the following optimization problem.

$$\min_w \frac{1}{b} \sum_{z \in B} \left( (1 - \rho) \ell(w, z) + \rho \frac{1}{k} \sum_{i=1}^k (\ell(w + \delta_i, z)) \right).$$

# Implication: GMP

---

## Algorithm 2 Gaussian Model Perturbation Training

---

**Require:** Training set  $S$ , Batch size  $b$ , Loss function  $\ell$ , Initial model parameter  $\mathbf{w}_0$ , Learning rate  $\lambda$ , Number of noise  $k$ , Standard deviation of Gaussian distribution  $\sigma$ , Lagrange multiplier  $\rho$

**while**  $\mathbf{w}_t$  not converged **do**

2: Update iteration:  $t \leftarrow t + 1$

Sample  $\mathcal{B} = \{z_i\}_{i=1}^b$  from training set  $S$

4: Sample  $\Delta_j \sim \mathcal{N}(0, \sigma^2)$  for  $j \in [k]$

Compute gradient:

$$g_{\mathcal{B}} \leftarrow \sum_{i=1}^b \left( \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, z_i) + \rho \sum_{j=1}^k (\nabla_{\mathbf{w}} \ell(\mathbf{w}_t + \Delta_j, z_i) - \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, z_i)) / k \right) / b$$

6: Update parameter:  $\mathbf{w}_{t+1} \leftarrow \mathbf{w}_t - \lambda \cdot g_{\mathcal{B}}$

**end while**

---

- ▶ Empirical evidence shows that a small  $k$  (e.g.,  $k = 3$ ) already gives competitive performance.
- ▶ Implementing the  $k + 1$  forward passes on parallel processors further reduces the computation load.

# Proof Sketch of Theorem 1 I

Recall that

$$|\text{gen}(\mu, P_{W_T|S})| \leq \sqrt{\frac{2R^2}{n} I(\tilde{W}_T; S)} + \left| \mathbb{E}_{W_T, S, S'} [\gamma(W_T, S) - \gamma(W_T, S')] \right|.$$

Notice that

$$\begin{aligned} I(\tilde{W}_T; S) &= I\left(\tilde{W}_{T-1} - \lambda_T g(W_{T-1}, B_T) + N_T; S\right) \\ &\leq I\left(\tilde{W}_{T-1}, -\lambda_T g(W_{T-1}, B_T) + N_T; S\right) \end{aligned} \quad (3)$$

$$= I(\tilde{W}_{T-1}; S) + I\left(-\lambda_T g(W_{T-1}, B_T) + N_T; S | \tilde{W}_{T-1}\right) \quad (4)$$

$\vdots$

$$\leq \sum_{t=1}^T I\left(-\lambda_t g(W_{t-1}, B_t) + N_t; S | \tilde{W}_{t-1}\right), \quad (5)$$

# Proof Sketch of Theorem 1 II

## Lemma 3

Let  $X, Y$  and  $\Delta$  be random variables which are all independent of  $N \sim \mathcal{N}(0, I)$ . Let  $Z = Y + \Delta$ , then for any  $\sigma$  and any function  $f$ , we have

$$I(f(Z, X) + \sigma N; X|Y) \leq \frac{1}{2\sigma^2} \mathbb{E} [ \|f(Z, X) - \mathbb{E}[f(Z, X)]\|^2 ]$$

Thus,

$$\begin{aligned} I(-\lambda_t g(W_{t-1}, B_t) + \sigma_t N; S | \tilde{W}_{t-1}) &\leq \frac{\lambda_t^2}{2\sigma_t^2} \mathbb{E} [ \|g(W_{t-1}, B_t) - \mathbb{E}[\nabla_w \ell(W_{t-1}, Z)]\|^2 ] \\ &= \frac{\lambda_t^2}{2\sigma_t^2} \mathbb{E} [\mathbb{V}_t(W_{t-1})] \end{aligned}$$

Putting everything together we have the bound in Theorem 1.

# Summary

- ▶ We derive tighter information-theoretic bounds for SGD
- ▶ Apply the bound to linear networks and two-layer ReLU networks
- ▶ Epoch-wise double descent of gradient dispersion is observed
- ▶ Design new regularization schemes, e.g., dynamic gradient clipping and GMP.

*Thanks for listening!*
